^^ * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Multiple imputation, specifically Predictive Mean Matching, was employed to assess the impact of missing data on outcomes. All key variables retained their directional effects and significance, with only minor fluctuations in magnitude. The sole exception is the “Student” variable, which exhibited a slight decrease in significance. The results indicate strong consistency between the two models, suggesting that missing data had minimal impact on the findings.
